1.1 Fourier Transforms of Bessel Functions (6 units) This project assumes only material contained in Part IA and Part IB core courses. Other than that, the project is self contained (although the Part II courses on Numerical Analysis, Further Complex Methods and Asymptotic Methods may provide relevant but non-essential background). 1 Introduction

1.1 Fourier Transforms of Bessel Functions (6 units)

The Fourier-Bessel series expansion employs aperiodic and decaying Bessel functions as the basis. The Fourier-Bessel series expansion has been successfully applied in diversified areas such as Gear fault diagnosis, discrimination of odorants in a turbulent ambient, postural stability analysis, detection of voice onset time, glottal closure instants (epoch) detection, separation of speech formants, EEG signal segmentation, speech enhancement, and speaker identification.

Lemma 1. The general solution of equation(1)in x >0is y(x) =A J (vx)+B Y (vx), where J and Y are, respectively, the Bessel functions of the rst and second kind of order α and A, B are constants. Moreover,limx→0+y(x)is nite if and only if B= 0and so y(x) =A J (vx). Proof.

The presence of the 12-fold rotational symmetry in the dielectric profile results in a 12-times reduction in the order of the matrix diagonalized when cast using the Fourier-Bessel basis functions. In addition, the Fourier-Bessel technique is highly suited for extracting the localized modes as it can be tuned to solve for a particular mode order.
